## **Project 3**

# Tanmay Singh tanmaypr@buffalo.edu

#### **Abstract**

The following report is an analysis of the accuracy in recognizing digits on using logistic regression, neural network ,Random Forest and SVM on MNIST and USPS datasets.

#### 1.Introduction

In project 2 we have been provided with two datasets MNIST dataset and USPS datasets. The datasets together provide information on whether the word is written by the same person or not. The human observed dataset consist of 9 features whereas the GSC dataset consist of 512 features.

#### **Confusion Matrix**

- -confusion matrix is a table that is used to describe how successful was the model in classifying the input values.
- -All the values that are along the diagonal from top left to bottom right are correctly predicted.
- -All the values that are in the lower part of the diagonal have actual value 1 but have been wrongly predicted as 0
- -All the values that are in the upper part of the diagonal have actual value 0 but have been wrongly predicted as 1.

The more number of values on the diagonal better is the model.

## 2.Neural Network

#### a)Hyperparameters

Neural Network model has the following hyperparameters

- -optimizers
- -number of hidden layers
- -number of nodes in hidden layers
- -dropout rate
- -loss

## Neural Networks

- -The loss is calculated using categorical cross-entropy since there are 10 classes we get the predicted values between 0 and 1. Each class is given a probability based upon which we can classify.
- -The number of nodes in the output layer is 10 since there are 10 classes from 0 to 9.
- We have to use softmax activation in the last layer since we need to classify the outputs in one of the 10 classes and the addition of all the probabilities should be 1.
- -We are performing one hot encoding of the input target matrix of MNIST and USPS dataset so that the target vector can be represented using binary values of 0 and 1. If the target is of the same class the value is 1 otherwise the value is 0.
- -We are getting the best results when the hyperparameters are as follow:-Number of Epooch-1000

Number of nodes in first hidden layer-128

Number of nodes in second hidden layer-128

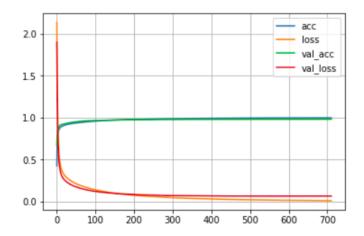

Batch size-32

we get the following accuracy values:

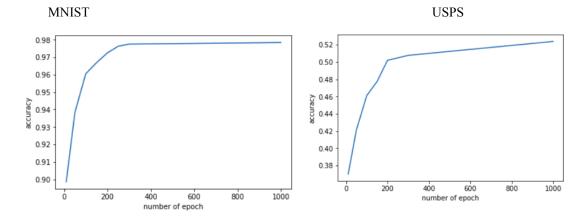

MNIST Training Accuracy:-0.999 Validation Accuracy:-0.9825

Testing Accuracy:-0.9784

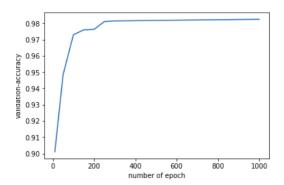

USPS Testing Accuracy:-0.5238

The testing accuracy plot and validation with different number of epoch,number of hidden layers are as follows

## validation accuracy

                               0.9784)
('Testing accuracy
                      mnist',
```

The neural network classifier gives the best result with the mnist testing accuracy of 97% as well as the usps testing accuracy of 52%. The diagonal elements of the mnist confusion matrix indicate that majority of the digits were correctly classified. The confusion for other classification has not gone in double digits in any instance.

## 3.Logistic Regression Model

- a) Hyper-parameters
- -Learning Rate
- -size of mini batch
- -number of iterations

#### Logistic Regression

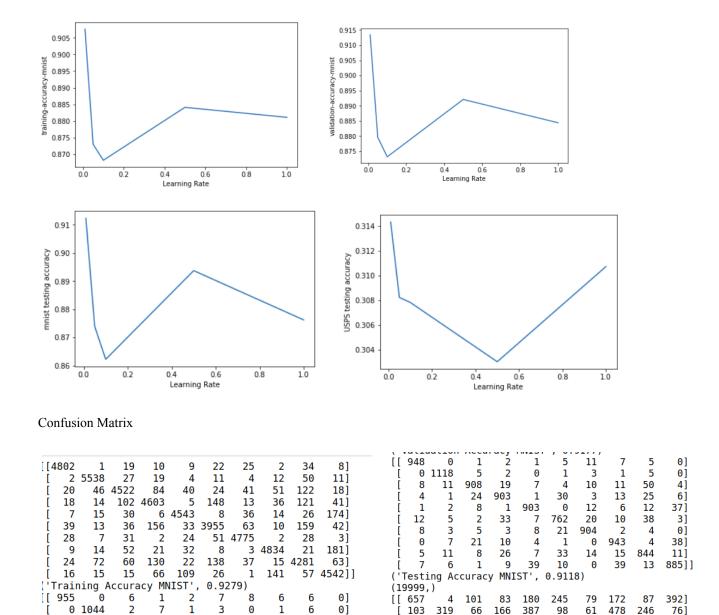

- Similar to neural network, logistic regression also uses softmax activation to make prediction for the given datasets.
- mini batch gradient descent is used in the logistic regression as it significantly increases the speed of the model.
- The gradient is being normalized in the model as the value is not the concern rather the direction of the descent is the concern because of this the speed of the model increases considerably.
- -The number of iterations significantly affects the performance since if the iterations are very high it might lead to over fitting of data.

We are getting the best results when the hyperparameters are as follows:

Learning Rate: 0.01 Size of mini batch: 100

MNIST Training accuracy:-0.9279 MNIST Validation accuracy:-0.9177 MNIST Testing accuracy:-0.9118 USPS Testing accuracy:-0.315515

The testing accuracy plot and validation with different Learning Rate, Batch size are as follows

The confusion matrix of the training mnist shows that there are some classes for which the confusion of the model is quite high but this is not the case with the confusion matrix of validation and testing datasets of mnist. The confusion matrix of the usps dataset is worse than that of neural network.

#### a)Hyperperameters

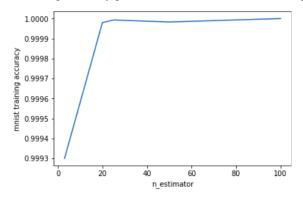

-no of estimators:- This gives the number of trees which are present in the forest

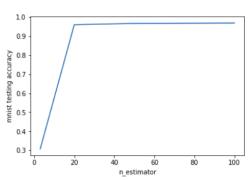

#### Random Forest Classifier

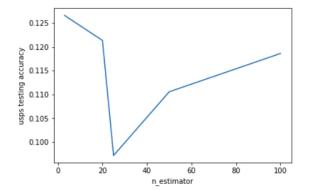

- -Random forest uses the dataset to create number of tress each classifying the input into one of the 10 classes.
- -There are n\_estimators number of trees present in the forest.

- -The final classification is done based on the mode of all the sub trees of the forest very similar to hard majority voting in ensemble.
- If the number of trees are very high it might lead to overfitting of data as well as the time required for computation will increase considerably.

The testing accuracy plot and validation with different n\_estimators are as follows:

#### **Confusion Matrix**

	('Te										

we can clearly see that the model is overfitted for the mnist dataset. We are getting a very high accuracy for mnist testing and very low accuracy for usps testing.

#### 4.SVM

a)Hyperparameters kernel gamma

## SVM

kernel-linear, radial basis function

## gamma-1,default

- -The compilation time of SVM is very high because of the calculation of the distance function
- SVM was compiled on google collab
- The accuracy for MNIST dataset is 0.9827
- -The accuracy for USPS dataset is 0.261413

## 5. Majority Voting

- In majority voting we take the predicted values of all the 4 models and create a matrix where each column is a prediction vector.
- -on each row we select that which occurs maximum number of times and we store it in our final ensembled prediction array.

We get the final testing accuracy as follows:-

MNIST:-97.1 USPS:-48.85244

we can clearly see that the ensembled predicted value for usps is better than all other models except the best predicted value of neural network.

#### **6.Free Lunch Theorem**

- -The free lunch theorem generally says that if a model is formed for a particular type of dataset and it gives a very good result on that model it is going to perform worse than random for other datasets.
- -our results perfectly support the free lunch theorem since in all the models we are able to get a very high accuracy with the mnist datasets but the model gives very poor accuracy for the usps datasets.
- -The accuracy for usps datasets is in the range of 30 to 40 which is worse than selecting randomly, for all the models except neural network where the accuracy is close to 50%.
